**ABSTRACT.** A new species of *Platystele* from northwestern Ecuador is described and illustrated. The new species, *Platystele finleyae*, belongs to the “pubescens” morphological informal group of species, and it is similar to *P. ximenae* in the broad flowers with pubescent sepals and petals but is easy distinguished by the vermilion to vinaceous flowers (vs. yellow, suffused with purple at the basal middle) and long ciliate petals (vs. shortly pubescent in *P. ximenae*). *Platystele finleyae* was found near Dracula Reserve, and it is named in honor of Elizabeth Finley Broaddus, who inspires many people, especially the youth, in environmental conservation. In addition, information is provided on its distribution, habitat, and conservation status.

**KEYWORDS/PALABRAS CLAVE:** Carchi, EcoMinga Foundation, Fundación Ecominga, mineria, mining, new orchid species, nueva especie de orquídea, Reserva Youth Land Trust.

America as far south as Bolivia and ranging in elevation from 300 to 3600 m with the greatest number of species known from Ecuador and Colombia (Baquero & Galarza Verkovitch 2019, Baquero & Zuchan 2017, Jost & Iturralde 2017, Karremans & Bogarín 2017, Romero et al. 2018, Thoerle 2018). Ecuador is considered the center of diversity for the genus with almost 60 species, of which 35 are considered endemic (Baquero & Galarza Verkovitch 2019, Baquero & Zuchan 2017, Jost & Iturralde 2017, Karremans & Bogarín 2017, Luer 1990, Reina-Rodríguez & Karremans 2018, Thoerle 2018). Ecuador is considered the center of diversity for the genus with almost 60 species, of which 35 are considered endemic (Baquero & Galarza Verkovitch 2019, Baquero & Zuchan 2017, Jost & Iturralde 2017, Karremans & Bogarín 2017, Luer 1990, Reina-Rodríguez & Karremans 2018, Thoerle 2018).

Species of *Platystele* can be easily recognized by their repent to caespitose plants, usually no more than 5 cm long, with petiolate, spatulate to obovate leaves, a filiform flower raceme which can be successively or simultaneously flowered, and varying from umbel late, congested, flexuous to distichous racemes borne at the base of the leaves and bearing miniature flowers, which are frequently flat, with free and spreading sepals and petals, a simple lip more or less cellular-glandular, with a basal glenion (Luer 1990). The column is short and wide, with an apical anther and a bilobed stigma (Karremans & Bogarín 2017, Luer 1990, Thoerle 2018).

A group of species endemic to the northwest of Ecuador and southwest of Colombia (Baquero & Galarza Verkovitch 2019, Kolanowska 2012, Luer 1990, 1991, 1994) shares a combination of unique features, including a broad, incurved, wide column (reminiscent of a tiny and wide human nose), pubescent, broad flowers with ciliate to long ciliate margins of the petals and sepals. These species would be included in the informal “pubescens” group based on the first species described, *Platystele pubescens* Luer. The species included in this informal group are *P. adelph*e Luer & Hirtz, *P. decouxii* Baquero & G. Verkovitch, *P. mucicola* Luer & Hirtz, *P. pubescens*, *P. scopulifera* Luer & Dodson, and *P. ximenae* Luer & Hirtz (Baquero & Galarza Verkovitch 2019, Luer 1990, 1991, 1994). In the past few years, new species of *Platystele* have been recorded in northwestern Ecuador, like *P. pamelae* Baquero & Zuchan, *P. cedriensis* Baquero & G. Verkovitch, and *P. decouxii* (Baquero & Galarza Verkovitch 2019, Baquero & Zuchan 2017). Here, we provide a detailed description, a line illustration, color figures, and information about the ecology, distribution, and conservation status of another new species of *Platystele* from northwestern Ecuador.

**Materials and methods.** Expeditions were made in March and August 2021 with botanists and zoologists of Instituto Nacional de Biodiversidad (INABIO), Fundación EcoMinga, and Reserva: The Youth Land Trust, to characterize the flora and fauna of the Dracula reserve and the Bosque Comunal La Esperanza, Carchi, Ecuador.

Fresh material of the new species was photographed *in situ* with a Canon EOS T6 camera and a Canon EF-S 35/28 Macro lens. It was subsequently pressed, dried, and deposited at QCNE as part of a research project on orchids under Research Permit No. MAAE-ARSFC-2021-1102. Digital images taken *in situ* and fresh flowers preserved in 70% ethanol and 1% glycerol, herbarium specimens (QCNE, QCA), specialized bibliography like Luer (1990), Baquero & Galarza Verkovitch (2019), Kolanowska (2012) and original descriptions of the related *Platystele* species were review and compared. The description and drawings were prepared from living specimens. Figures and a composite digital line drawing were prepared based on the type specimen images using Adobe Photoshop® 2019. The distribution map was prepared using ArcGis Desktop 10.8.

**Taxonomic treatment**

*Platystele finleyae* M.F.Monteros, E.Restrepo & Baquero, sp. nov. (Fig. 1–4).

**TYPE:** Ecuador. Carchi: La Esperanza, 1700m, 0°56‘11.14” N, 78°14’33.86” W, 24 March 2021, M. Monteros 209 (holotype: QCNE!).

**Diagnosis:** *Platystele finleyae* is most similar to *Platystele ximenae* from which it can be easily distinguished by its vermilion to vinaceous flowers (vs. yellow, suffused with purple at the basal middle), with long ciliate petals (vs. shortly pubescent) and the elliptical-oblong lip (vs. transversely cordate).

**Plant** small, epiphytic, caespitose herb, up to 5 cm including inflorescence; *roots* slender *ca*. 0.3 mm in di-

Monteros (A–C, F) & Andrés Better (D–E) from the plant that served as the holotype (MFM 209, QCNE). Prepared by Eugenio Restrepo.
Monteros et al. — A new Platystele from Ecuador

Ramicauls erect to suberect, slender, 3–4 mm long, enclosed by 1–2 thin, ribbed, imbricating sheaths. Leaf erect to suberect, coriaceous, obovate, with the base narrowly attenuated into a petiole, 2.0–3.0 × 0.7–1.1 cm. Inflorescence erect and successively-flowered raceme, 3–5 cm long, including filiform peduncle 0.5 cm long, emerging low from the ramicaul; floral bracts acuminate, 1 mm long; pedicels 2.5 mm long. Ovary 6-ribbed, 1 mm long. Sepals vermilion to vinaceous, glabrous towards the basal half and sparsely pubescent towards the apex, ciliate on the margins. Dorsal sepal broadly oblong, attenuate, long ciliate in the margins, subconvex, 1-veined, 2.0–2.5 × 1.5 mm. Lateral sepals broadly ovate, obtuse, slightly ciliate in the margins, connate at the base, 1-veined, 2.0 × 2.5 mm. Petals vermilion to vinaceous, oblanceolate, subfalcate, glabrous, acute, 2.0 × 1.0 mm, 1-veined, long-ciliate from the middle to the apex. Lip flame-colored, oblong, elliptical, cellular-glandular, small delicate glenion at the base, with a rounded apex, 1.1 × 0.9–1.0 mm, with the rounded base inflexibly attached to the column. Column flame-colored to cream, short, incurved, stout semiterete 0.6 × 0.5 mm, anther ventral with the stigma subapical, reflexed, transversely bilobed on each side of the anther, the foot rudimentary. Anther cap yellowish, obovate, cucullate, 0.3 mm long. Fruits not seen.

Paratype: Ecuador. Carchi: La Esperanza, 1700m, 0°56′11.03″ N, 78°14′33.91″ W, 2 August 2021, M. Monteros 210 (QCNE!).

Eponymy: The name honors Elizabeth Finley Broadinus, a young nature lover who inspired thousands of people to take action to conserve nature and fight...
against climate change. She set up her foundation, Finley’s Green Leap Forward, to support local and global efforts that positively impact the environment. Further to encouraging individual action, Finley’s efforts served as the inspiration behind the foundation of Reserva: The Youth Land Trust. This nonprofit organization has since established the world’s first youth-funded nature reserve in northwestern Ecuador.

HABITAT AND ECOLOGY: *Platystele finleyae* was found growing in a poorly explored forest of northwestern Ecuador, near the limit of Fundación EcoMinga’s Dracula Reserve, around 1711 m of elevation. According to the Ministerio del Ambiente del Ecuador (2013), this ecosystem is classified as a lower montane evergreen forest of the western Andes (BSBN04). This region of Ecuador is characterized by high biodiversity because it is influenced by two of the world’s most diverse hotspots: Tumbes-Choco-Magdalena and Tropical Andes. *Platystele finleyae* grows epiphytically and shares the habitat with other Pleurothallidinae species such as *Scaphosepalum swertiifolium* Rchb.f., *Masdevallia picturata* Rchb.f., and *Lepanthes hexapus* Luer & R.Escobar.

PHENOLOGY: Plants of the species have been observed flowering in situ in March and August.

*Platystele finleyae* has flowers morphologically similar to *P. ximenae* in the pubescent flowers with broad, connate at the base, lateral sepals, and the lip with basal lobes surrounding the column (Fig. 3B,E, 4B), but it is easily distinguished by the obovate leaves (vs. narrowly elliptical), the vermilion to vin-

---

**Figure 5.** Other species of *Platystele* that have been recorded around the locality of *Platystele finleyae* M.F.Monteros, E.Restrepo & Baquero. A. *Platystele baqueroi* Jost & Iturralde. B. *Platystele hirtzii* Luer. C. *Platystele caudatisepala* (C.Schweinf.) Garay. D. *Platystele filamentosa* Luer. E. *Platystele pamelae* Baquero & G.Verkovitch. E. *Platystele cf. alucitae* Luer. Photographs by Marco Monteros (A, B) and Luis Baquero (C–F). Prepared by Eugenio Restrepo.
ceous color of the flowers and its pattern (vs. yellow, suffused with purple towards the basal middle); the dorsal sepal broadly oblong, attenuate, long ciliate in the margins, subconvex (vs. elliptical, obtuse, shortly acuminate), and the lateral sepals obtuse, and slightly ciliate at the margins (vs. broadly ovate, oblique, obtuse, shortly acuminate, shortly pubescent). It also differs from *P. ximenae* by the integument of the petals, which is long ciliated (vs. short trichomes over the inner surface and margins, absent at the base), and the flame-colored lip, which is oblong, elliptical, rounded (vs. brown, transversely cordate, obtuse), narrower (0.9–1.0 mm vs. 1.4 mm), inflexibly attached to the column at the base (vs. with the basal lobes incurved and embracing the column).

*Platystele finleyae* appears to be related to other species belonging to the “pubescens” morphological informal group, like *P. adelpha*, *P. decouxii*, *P. muscicola*, *P. pubescens*, *P. scopulifera*, and *P. ximenae* (Baquero & Galarza Verkovitch 2019, Luer 1990, 1991, 1994). All these species are distributed in the biogeographic region of the western Andes of Ecuador and the southwestern Andes of Colombia in the Department of Valle del Cauca (Baquero & Verkovitch 2019, Kolanowska 2012, Luer 1990, 1994, Ministerio del Ambiente del Ecuador 2013). Most of these species are endemic to the biogeographic region of the Tropical Andes. Presumably, the highest diversity of this morphological informal group is restricted to the northwestern provinces of Carchi, Esmeraldas, and Imbabura, where *Platystele adelpha*, *P. decouxii*, *P. muscicola*, *P. pubescens*, *P. scopulifera*, *P. ximenae*, and *P. finleyae* grow (Fig. 6).

Other species of *Platystele* are known to be close to the locality of *Platystele finleyae*, such as *P. alucitae* Luer, *P. caudatissipala* (C.Schweinf.) Garay, *P. filamentosasa* Luer, *P. hirtzii* Luer, and *P. pamelae* Baquero & Zuchan (Baquero & Zuchan 2017, Jost & Iturralde 2017, Luer 1990), but none of them are morphologically similar to *P. finleyae* (Fig. 5).
Even though the Cordillera Occidental de Ecuador is an important biogeographic region for Ecuadorian biodiversity, it is currently strongly threatened by mining concessions, the lack of government-owned protected areas, and the illegal extraction of species. These threats put the conservation status of these species at risk (Monteros et al. 2021, Yáñez-Muñoz et al. 2021). Therefore, it is necessary to evaluate their conservation status according to IUCN criteria, to focus on effective conservation actions (Fig. 6).

**Conservation status:** Although not yet evaluated, we suggest classifying this species as “Critically Endangered” following (IUCN 2012) criteria B2ab(iii): area of occupancy estimated to be less than 10 km²; known to exist in no more than one locality, even though constant explorations have been carried out in this region during the last five years (Baquero & Monteros 2020, Baquero & Zuchan 2017, Jiménez et al. 2018, Monteros et al. 2021) and continuing decline, observed, inferred or projected, in area, extent, or quality of habitat. The main threats to this species are abrupt microclimate variations, habitat loss, and mining projects in the region (Fig. 6).

**Acknowledgments.** We acknowledge Fundación EcoMinga, Rainforest Trust, Orchid Conservation Alliance, and Reserva: The Youth Land Trust for their support and their hard conservation work in northwestern Ecuador. We thank Javier Robayo, Callie Broaddus, Julio César Carrión, Andrés Better, and Lucy Houliston for the support and collaboration in the field during the expeditions in Dracula Reserve. Thanks to Chiara Correa for her unconditional support. We thank Universidad de Las Américas (UDLA) for funding orchid research in Ecuador. The Ministerio del Ambiente del Ecuador is acknowledged for issuing the Environmental Research Permit No MAAE-ARSC-2021-1102. We also thank the INABIO, especially Mario Yáñez, Jorge Brito, Mauricio Herrera, and Miguel Urgilés, for their help and excellent biogeographic discussions in the field. The authors thank Lou Jost for his valuable suggestions to improve the manuscript. Finally, we are grateful to the Editor and anonymous reviewers for the suggestions on the manuscript.
